

Invention disclosure and claims

Document: INL-2026-CLAIMS.PORTAL.PHONEAI.001

Effective date of public disclosure: 31 August 2026

Inventor: Alfredo Medina

Operating names: ItsNotAI Labs · Medina Tech Labs

Assignee (intended): ItsNotAI Labs

Public prior-art deposit: <https://github.com/ItsNotAILABS/pocket> · <https://github.com/ItsNotAILABS/PhoneAI> · <https://github.com/ItsNotAILABS/phoneai-desk>

This is a defensive publication. It puts the inventions below into the public record under the inventor's name so others cannot patent them out from under him. It is not itself a filed patent application. Rights to file patents on improvements are reserved.

Working embodiment: POCKET host ``:8787`` (version 3.8+) on an operator PC, PhoneAI kernel at ``/phoneai``, first-class Portal stream at ``/phoneai/portal``, Antigravity desktop-app view at ``/phoneai/anti``.

Field

A local multi-agent operating system on a personal computer, controlled from a phone, including live visual streaming of the real desktop and touch-to-pointer mapping, plus a separate control surface for an existing desktop coding-agent application (Antigravity), without collapsing those two products into one screen.

Background (what is new)

Remote desktop products stream a PC and accept touch. Chat products talk to models. Agent IDEs hold project threads. None of them, as embodied here:

1. treat the phone as a first-class kernel seat distinct from the PC owner login;
2. mint a per-account twin workspace (files, embedded CLIs, dual encrypted vaults) on *the operator's PC*;
3. expose studios as agent tools (WebMCP) rather than extra human screens;
4. name live Antigravity trajectories from real worktrees harvested from on-disk SQLite, while keeping Antigravity a desktop app view, not the whole-PC stream;
5. provide a first-class Portal that streams the real virtual desktop and maps normalized phone coordinates onto that desktop's mouse, coalesced so the host cannot flood itself;
6. refuse to nest the host's own Grok CLI into the live operator session (deadlock prevention).

Those six are claimed below as a system and as independent methods.

Independent claims

Claim 1. Phone kernel seat. A method of operating a multi-agent host on a personal computer comprising: maintaining an owner principal for the host; minting a distinct phone-kernel principal (``phoneai``) with its own tenant directory, credentials, and explorer tree; and serving a phone-native OS surface from the same host process without a separate document database.

Claim 2. Twin mint on the operator machine. A method comprising: on registration of a seat, allocating on the host filesystem a twin tree containing a working folder, embedded CLI shims for a plurality of model agents, an encrypted vault, and a copy of that vault into a host-side vault path, such that agents run with ``PATH`` pointing at that tree rather than a global install.

Claim 3. Think-first routing. A method of agent dispatch comprising: classifying an utterance into at most one engine and at most one tool; defaulting to a chat engine with no tool; and invoking develop, ship, mint, or session tools only when the utterance explicitly requests them.

Claim 4. WebMCP work functions, not extra screens. A system in which develop studios, ship studios, twin operations, Antigravity send/continue, and GO-plane sync are registered as catalogued actions an agent may invoke in the same work loop as chat, without requiring a human to navigate a separate studio URL.

Claim 5. First-class visual Portal with touch-to-desktop. A method comprising: capturing a JPEG of the operator PC's virtual desktop; serving that frame to a phone; mapping a normalized touch coordinate ``(nx, ny)`` in ``[0,1]^2`` onto the virtual-screen rectangle ``(x, y, w, h)`` obtained from the OS; and synthesizing native mouse events (move, down, up, wheel) at the mapped pixel, with grab coalescing so concurrent clients share a recent frame.

Claim 6. LAN-bounded embodiment of Claim 5. The method of Claim 5 wherein synthesizing mouse events is permitted only for loopback or same-LAN clients and is denied for public-internet and reverse-proxy clients.

Claim 7. Antigravity as a separate desktop-app surface. A method comprising: enumerating on-disk Antigravity conversation databases; deriving a human title from worktree and GitHub path strings inside trajectory blobs (not from opaque identifiers); presenting that list on a phone view dedicated to the Antigravity desktop application; and sending text into that application via UI automation — without using that view as the whole-PC Portal of Claim 5.

Claim 8. Nested-session exclusion. A method of running a phone agent on a host that is itself being driven by a live Grok (or similar) session, comprising: stripping inherited session environment from child processes; refusing to ``--resume`` the live session identifier; and answering the phone from a local path so the live session is not deadlocked.

Claim 9. Dual write to sovereign git and public GitHub. A method wherein a phone-kernel note or work artifact is written to (a) a tenant explorer folder, (b) a local sovereign git repository, and (c) a queued push to a public GitHub vault associated with the lab, under the phone-kernel identity.

Claim 10. Combined system. A host computer running POCKET that simultaneously exposes: Claim 1 seat, Claim 5 Portal, Claim 7 Antigravity view, Claim 3 routing, and Claim 4 WebMCP, as separately addressable first-class surfaces (``/phoneai``, ``/phoneai/portal``, ``/phoneai/anti``) on one local HTTP host.

Dependent claims (selected)

- 5.1 Frame capture uses a process-wide lock and a time-to-live cache (about 300 ms) so stacked HTTP clients cannot spawn unbounded ``ImageGrab`` work.
- 5.2 The phone UI requests the next frame only after the previous image ``load`` or ``error``, and pauses when the document is hidden.
- 5.3 Touch kinds include tap, drag, right-click, scroll, and type-into-focus.

- 7.1 Titles are of the form `App — Task` derived from `~/gemini/antigravity/worktrees/...`.
- 7.2 The Antigravity view lists live threads and can open, new-chat, continue, and send without attaching to the Portal stream.
- 2.1 Vault envelopes use `hmac-sha256-ctr-v1`.
- 8.1 Pocket session ids (`s-...`, `pa-...`) are not treated as Grok resume ids.

Inventorship and lab

Alfredo Medina conceived and directed the reduction to practice on the reference operator PC in Dallas, August 2026, through ItsNotAI Labs / Medina Tech Labs. Embodiments are in the public GitHub repositories named above (Pocket 3.8+; PhoneAI kernel; phoneai-desk vault).

Do not assign these claims to a third party without a written instrument from the inventor.
